# A Brief Tutorial on Inter-Rater Agreement

**Christian M. Meyer** 

Based on a tutorial on inter-rater agreement held as part of the doctoral program "Language and Knowledge Engineering" (LKE) at the Technische Universität Darmstadt, Germany on November 9, 2009 by Christian M. Meyer. All described measures have been implemented in DKPro Agreement. https://code.google.com/p/dkpro-statistics/

# **Introduction** Validity, Reliability, Agreement

For each (manually or automatically generated) dataset, it is crucial to consider the following questions:

Is my evaluation valid?	Is my evaluation data reliable?	What is good agreement?	
<ul> <li>Can we draw conclusions from the data?</li> </ul>	<ul> <li>Is the generation reproducible?</li> <li>Raters annotate a</li> </ul>	<ul> <li>How to measure agreement?</li> </ul>	
One prerequisite	sample of the data	<ul> <li>How to interpret the result?</li> </ul>	
for <b>validity</b> is that the evaluation data is <b>reliable</b> .	<ul> <li>Assumption: The data is reliable if their agreement is good.</li> </ul>	<ul> <li>Inter-rater agreement coefficients</li> </ul>	

# Introduction Notation

	$m$ raters $r \in R$ aka. coders, annotators, observers,				
matching?	yes	yes	no		
score for	low	medium	low	<u>к</u> а	
Apple	NN	NNP	NN	•	
bass	WN1	WN2	WN1	•	

*n* items *i* ∈ *I* aka. units, records,...

>50 years of agreement studies – >50 different notation schemas!

k categories  $c \in C$  aka. labels, annotations,..., which can be:

- binary (yes, no)
- ordinal (1, 2, 3,...)
- continuous (0.03, 0.49,...)
- ordered-category (low, high)
- nominal (NN, NNP, JJ, VB)
- likert-scale (strongly disagree, disagree, agree, strongly agree)

# Percentage of Agreement Definition

Contingency	Matrix:
Containgonioy	

	r1 high	r1 low	
r2 high	2	2	4
r2 low	1	5	6
	3	7	10

#### **Percentage of agreement:**

 $A_0 = 1/n \Sigma_c (\# of agreements)$  $A_0 = 1/10 (2 + 5) = 0.7$ 

Relatedness?	r1	r2
gem – jewel	high	high
coast – shore	high	high
coast – hill	high	low
forest – graveyard	low	high
asylum – fruit	low	low
noon – string	low	low
automobile – wizard	low	low
brother – lad	low	high
cord – smile	low	low
autograph - shore	low	low

Example word pairs taken from Rubenstein & Goodenough (1965). Calculation example is inspired by Artstein & Poesio (2008).

# **Percentage of Agreement** Standard Error and Confidence Interval

**Contingency Matrix:** 

	r1 high	r1 low	
r2 high	2	2	4
r2 low	1	5	6
	3	7	10

# Percentage of agreement:

 $A_0 = 1/n \Sigma_c (\# of agreements)$  $A_0 = 1/10 (2 + 5) = 0.7$ 

# Standard error:

$$\begin{split} SE(A_{o}) &= \sqrt{A_{o} \left(1 - A_{o}\right)} \, / \, n \\ SE(A_{o}) &= \sqrt{0.7 \left(1 - 0.7\right)} \, / \, 10 = 0.04 \end{split}$$

# **Confidence intervals:**

 $CL = A_0 - SE(A_0) \cdot zCrit$   $CU = A_0 + SE(A_0) \cdot zCrit$   $0.610 \le 0.7 \le 0.789$ with *zCrit* = 1.96 (95% confid.)  $0.624 \le 0.7 \le 0.775$ with *zCrit* = 1.645 (90% confid.)

#### **Issues** Why is there Disagreement at all?

# Sources of disagreement:

- Insecurity in deciding on a category
- Hard/Debateable cases
- Carelessness
- Difficulties or differences in comprehending instructions
- Openness for distractions
- Tendency to relax performance standard when tired
- personal opinions/values

# **Possible corrective actions:**

- **Training** of the annotators
- Write better instructions
- Provide better environment
- Reduce amount of annotated data per annotator
- Use more annotators

• . . .

# **Issues** Agreement by Chance

- Percentage of agreement does not regard agreement by chance
- Imagine the raters would guess randomly:

	r1 high	r1 low	
r2 high	45	45	90
r2 low	45	45	90
	90	90	180

 $A_0 = 1/180 (45 + 45) = 0.5$ 

 $A_0 = 1/180 (20 + 20 + 20) = 1/3$ 

One would assume similar agreement → use chance-corrected measures!

# **Issues** Equal Weights

# All categories are treated equally

Consider annotating/marking proper nouns in arbitrary texts

	r1 +	r1 –	
r2 +	10	20	30
r2 –	20	1,000	1,020
	30	1,020	1,050

Almost perfect agreement, although the actual proper noun identification did not really work!

 $A_0 = 1/1050 \; (10 + 1000) = 0.961$ 

For binary data: calculate positive and negative agreement

 $A_{0+} = 2 \ (\# \ of \ agreements \ for \ +) \ / \Sigma_r \ (\# \ of \ + \ annotations)$  $A_{0+} = 2 \cdot 10 \ / \ (30 + 30) = 0.333$ 

 $A_{0-} = 2 \ (\# \ of \ agreements \ for \ -) \ / \Sigma_r \ (\# \ of \ - \ annotations)$  $A_{0-} = 2 \cdot 1000 \ / \ (1020 + 1020) = 0.980$ 

(Cicchetti and Feinstein, 1990)

<b>Issues</b> Summary			TECHNISCHE UNIVERSITÄT DARMSTADT
Measure	chance-corrected agreement	multiple raters	weighted categories
Percentage of Agreement	×	×	×

# Chance-corrected Measures Definition

Basic idea:  $agreement = \frac{agreement beyond chance}{attainable chance-corrected agreement} = \frac{A_0 - A_E}{1 - A_E}$ 

Bennett, Alpert & Goldstein (1954)

$$S = \frac{A_O - A_E^S}{1 - A_E^S}$$

assume **uniform** distribution, i.e. the same probabilities for each categories:

$$A_E^{S} = \frac{1}{k}$$

Scott (1955)

$$\pi = \frac{A_0 - A_E^{\pi}}{1 - A_E^{\pi}}$$

assume a **single distribution for all raters**, i.e. each rater annotates the same way:

$$A_E^{\pi} = \frac{1}{4n^2} \Sigma_c n_c^2$$

with the total number of annotations  $n_c$  for category c by all raters.

Cohen (1960)

$$\kappa = \frac{A_O - A_E^{\kappa}}{1 - A_E^{\kappa}}$$

assume **different probability distributions** for each rater:

$$A_E^{\kappa} = \frac{1}{n^2} \sum_c n_{c,r1} n_{c,r2}$$

with the total number of annotations  $n_{c,r}$  for category c by rater r.

# Chance-corrected Measures Example

Basic idea: agreement =  $\frac{A_0 - A_E}{1 - A_E}$ 

	r1 high	r1 low	
r2 high	2	2	4
r2 low	1	5	6
	3	7	10

Bennett et al.'s *S*:  $A_E^{S} = 1 / 2 = 0.5$ S = (0.7 - 0.5) / (1 - 0.5) = 0.4

Scott's 
$$\pi$$
:  
 $A_E^{\pi} = 1/(4 \cdot 10^2) ((3 + 4)^2 + (6 + 7)^2)$   
 $= 0.545$   
 $\pi = (0.7 - 0.545) / (1 - 0.545) = 0.341$ 

#### **Percentage of agreement:**

 $A_0 = 1/n \Sigma_c (\# of agreements)$  $A_0 = 1/10 (2 + 5) = 0.7$ 

**Cohen's** 
$$\kappa$$
:  
 $A_E^{\kappa} = 1/10^2 (3 \cdot 4 + 6 \cdot 7) = 0.54$   
 $\kappa = (0.7 - 0.54) / (1 - 0.54) = 0.348$ 

# **Issues** Agreement by Chance

- Percentage of agreement does not regard agreement by chance
- Imagine the raters would guess randomly:

	r1 high	r1 low	
r2 high	45	45	90
r2 low	45	45	90
	90	90	180

	r1 high	r1 med	r1 low	
r2 high	20	20	20	60
r2 med	20	20	20	60
r2 low	20	20	20	60
	60	60	60	180

$$A_0 = 0.5$$
  $A_0 = 1/3$ 

S = 0.0 $\pi = 0.0$ $\kappa = 0.0$	<b>Chance-corrected!</b> $\pi$	= 0.0 = 0.0 = 0.0
--	--------------------------------	-------------------------

Example word pairs taken from Rubenstein & Goodenough (1965).

# Multiple Raters Generalized Measures

- So far, we only considered two raters, although there are usually more
- Generalize two-rater measures:

### Fleiss (1971)

Generalizes Scott's  $\pi$ . The basic idea is to consider each pairwise agreement of raters and average over all items *i*.

$$multi - \pi = \frac{A'_{0} - A'_{E}\pi}{1 - A'_{E}\pi}$$
$$A'_{0} = \frac{1}{nm(m-1)} \sum_{i} \sum_{c} n_{i,c} (n_{i,c} - 1)$$
$$A'_{E}\pi = \frac{1}{(nm)^{2}} \sum_{c} n_{c}^{2}$$

with the total number of raters  $n_{i,c}$  that annotated item *i* with category *c*.

### Davis and Fleiss (1982)

Generalizes Cohen's  $\kappa$ . The basic idea is to consider each pairwise agreement of raters and average over all items *i*.

$$multi-\kappa = \frac{A'_O - A'_E^{\kappa}}{1 - A'_E^{\kappa}}$$

$$A'_{0} = \frac{1}{nm(m-1)} \Sigma_{i} \Sigma_{c} n_{i,c}(n_{i,c} - 1)$$

$$A_{E}^{\prime \kappa} = \Sigma_{c} \ \frac{1}{\binom{m}{2}} \Sigma_{r1=1}^{m-1} \Sigma_{r2=r1+1}^{m} \frac{n_{r1,c} n_{r2,c}}{n^{2}}$$

with the total number of annotations  $n_{c,r}$  by rater *r* for category *c*.

# **Multiple Raters** Example for $multi-\pi$

			3	· 2 + 0 · (-	-1)
Fleiss (1971)	$\Sigma_{\rm c}  {\rm n}_{\rm i,c} ({\rm n}_{\rm i,c} - 1)$	Item	high	low	
$A'_{0} = \frac{1}{nm(m-1)} \sum_{i} \sum_{c} n_{i,c} (n_{i,c} - 1)$	6	1	3	0	
	2	2	2	1	
$A'_0 = \frac{1}{10 \cdot 3(3-1)}  32 = 0.533$	2	3	2	1	
	2	4	2	1	
$A'_E{}^{\pi} = \frac{1}{(nm)^2} \Sigma_c n_c^2$	2	5	1	2	
$A'_{E}{}^{\pi} = \frac{1}{(10\cdot 3)^{2}} (13^{2} + 17^{2}) = 0.508$	6	6	0	3	
(10,3)2	6	7	0	3	
multi- $\pi = \frac{A'_{0} - A'_{E}\pi}{1 - A'_{\pi}\pi} = 0.049$	2	8	1	2	
$1 - A_E^{\prime} \pi$	2	9	1	2	
<i>multi-</i> $\pi$ is also known as $\kappa$ (Fleiss, 1971) and	2	10	1	2	
<i>K</i> (Carletta, 1996) – check definition!	32	n <sub>c</sub>	13	17

# Krippendorff's $\alpha$ Definition

Allow further flexibility by allowing arbitrary category metrics.

# Krippendorff (1980)

Derived from empirically statistics and content analysis. But can be represented in the same notation.

 $\alpha = 1 - \frac{D_0^{\alpha}}{D_E^{\alpha}} = \frac{\text{'est. var. within items'}}{\text{'est. total variance'}}$  $D_0^{\alpha} = \frac{1}{nm(m-1)} \sum_i \sum_{c_1} \sum_{c_2} n_{i,c_1} n_{i,c_2} \underline{d_{c_1,c_2}}$ 

$$D_{E}^{\ \alpha} = \frac{1}{nm(nm-1)} \sum_{c1} \sum_{c2} n_{c1} n_{c2} \frac{d_{c1,c2}}{d_{c1,c2}}$$

with the total number of raters  $n_{i,c}$  that annotated item *i* with category *c* and the total number of annotations  $n_c$  for category *c* by all raters.

# Distance function $d_{c1,c2}$

Arbitrary metric to allow working with

#### binary or nominal data:

 $d_{c1,c2} = (c1 == c2 ? 0 : 1)$ with this distance function:  $\alpha \approx \pi$ 

ordinal data ('square distance func.'):  $d_{c1,c2} = (c1 - c2)^2$ 

#### weighted data:

d <sub>c1,c2</sub>	NN	NNP	VB
NN	_	0.1	0.9
NNP	0.1	-	0.9
VB	0.9	0.9	_
	_	_	

as well as interval, ratio data.

# Krippendorff's $\alpha$ Example

<i>n</i> <sub>c1,c2</sub>	<b>r1</b> ·	+	<b>r</b> 1	•		·1 –			
r2 +	46	)		0		6		52	
r2 ●	0		1	0		6		16	
r2 –	0			0		32		32	
	46	;	1	0		44		100	$\mathbf{N}$
									-
<b>d</b> <sub>c1,c2</sub>	r1 +	r1	•	<b>r1</b>	-	С		n <sub>c</sub>	/
r2 +	0.0	0	.5	1.	0	+		98	/
r2 ●	0.5	0	.0	0.	5	•		26 🎽	
r2 –	1.0	0	.5	0.	0	-		76	
									22
$n_{c1}n_{c2}$	<i>d</i> <sub><i>c</i>1,<i>c</i>2</sub>		r1 +		<b>r</b> 1	•		r1 –	>
r2	+	0		0 1		74	7	448	
r2	•	1274			(	)	9	988 🖌	
r2	-	7	<b>'</b> 448	6	98	38		0	

$$D_{0}^{\alpha} = \frac{1}{nm(m-1)} \sum_{i} \sum_{c2} \sum_{c2} n_{i,c1} n_{i,c2} d_{c1,c2}$$

$$D_{0}^{\alpha} = \frac{46 \cdot 0 + 10 \cdot 0 + 6 \cdot 1 + 6 \cdot 0.5 + 32 \cdot 0}{100 \cdot 2(2-1)}$$

$$= 0.09$$

$$D_{E}^{\alpha} = \frac{1}{nm(nm-1)} \sum_{c1} \sum_{c2} n_{c1} n_{c2} d_{c1,c2}$$

$$D_{E}^{\alpha} = \frac{1274 + 7448 + 1274 + 988 + 7448 + 988}{100 \cdot 2(100 \cdot 2 - 1)}$$

$$= 0.4879$$

Krippendorff (1980)

$$\alpha = 1 - \frac{D_0^{\alpha}}{D_E^{\alpha}} = 1 - \frac{0.09}{0.4879} = 0.8155$$

# **Issues** Summary

Measure	chance-corrected agreement	multiple raters	weighted categories
Percentage of Agreement	<b></b>	×	×
Chance-corrected S	$\checkmark$	×	×
Scott's $\pi$	$\checkmark$	×	×
Cohen's <i>k</i>	$\checkmark$	×	×

multi-ĸ	$\checkmark$	$\checkmark$	×
Krippendorff's $\alpha$	$\checkmark$	$\checkmark$	$\checkmark$
Weighted $\kappa$ (not covered here)	$\checkmark$	$\checkmark$	$\checkmark$

# Side Note: Criticism "The Myth of Chance-Corrected Agreement"

- Chance-corrected measures have also been criticized
- The presented measures S, π, κ assume that the raters are completely statistically independent
  - This means (1) the raters guess on every item or (2) the raters guess with probabilities similar to the observed ratings.
  - (1) is clearly not valid for an annotation study
  - (2) would not need a chance-correction
- Another argument is the different approach when comparing to a gold standard 

   measure precision/recall without any chance-correction
- John Uebersax proposes using raw agreements and focus on statistic significance tests, standard error and confidence intervals
- cf. (Uebersax, 1987; Agresti, 1992; Uebersax, 1993)

# **Traditional Statistics**

Why not use  $\chi^2$  or correlations?

TECHNISCHE UNIVERSITÄT
DARMSTADT

	r1 +	r1 ●	r1 –	
r2 +	25	13	12	50
r2 ●	12	2	16	30
r2 –	3	15	2	20
	40	30	30	100

$\chi^2 = 64.59$
$A_0 = 0.36$ S = 0.04
$\pi = 0.02$
$\kappa = 0.04$

 $\chi^2$  is highly significant, because of the strong **associations** 

The **agreement** is however low!

Adapted from Cohen (1960)

Α	В
1	1
2	2
3	3
4	4
5	5

Pearson correlation rvs. Cohen's  $\kappa$ : r = 1.0 r = 1.0 $\kappa = -0.08$ 

**Correlation measures are** 

not suitable to measure

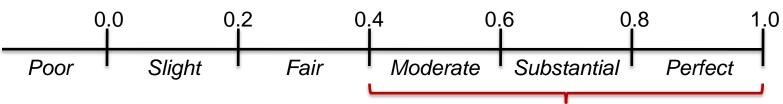

inter-rater agreement!

# Interpretation What is good agreement?

# Landis and Koch (1977)

# Krippendorff (1980), Carletta (1996)

- 0.67 < K < 0.8 "allowing tentative conclusions to be drawn"</p>
- above 0.8 "good reliability"

# Krippendorff (2004)

"even a cutoff point of 0.8 is a pretty low standard"

# Neuendorf (2002)

 "reliability coefficients of 0.9 or greater would be acceptable to all, 0.8 or greater [...] in most situations"

# Recommendations

by Artstein and Poesio (2008)

- 1. Anything is better than nothing
- 2. Give **details** on your study (who annotates and how?)
- 3. Use intensive training or professionals annotators
- 4. Report also the **agreement table/contingency matrix** rather than only the obtained agreement
- 5. Annotate with as **many raters** as possible, since it reduces the difference between the measures
- 6. Use *K* (equal to *multi-* $\pi$ ) or  $\alpha$  which are used in the majority of studies, allow comparison and solve chance-related issues
- 7. Use Krippendorff's  $\alpha$  for category labels that are not distinct from each other (**custom distance function**)
- 8. Be careful with **weighted measures** as they are **hard to interpret**
- 9. Agreement should be **above 0.8** to ensure data reliability (but depends on the case)
